WHAT THIS DATA MEANS FOR EACH DEPARTMENT

Two seasons of training load, wellness and injury data from two elite women's football teams (SoccerMon, 2020-2021), analysed in Power BI and R. Each row below gives one department the finding that matters most to them and one practical suggestion. Full details are in the report.

Department	What the data shows	Suggestion
Physiotherapy	Knees made up 38% of injury reports (116 of 306) and 70 of the 76 major reports. Injury records show how long a player reported symptoms, not time lost: one player logged a major knee injury once, then trained at zero load for a week; another logged an injury for 163 days while training normally.	Record a daily availability status (full, modified, unavailable) alongside symptoms, so time lost and return-to-training progress can actually be measured. Review knee injuries together to look for common mechanisms.
Strength & Conditioning	ACWR was above 1.5 on 14% of training days (Team B 17.8%, Team A 12.1%), and monthly squad load rose almost threefold from the winter break to pre-season. A 600 AU session adds only about 0.1 points of next-day fatigue compared with 300 AU.	Plan graded build-ups after breaks and review players above 1.5 in the weekly report. Expect a slightly lower wellness score after a hard session; act on a player who stays below her normal for a week.
Psychology	Stress is one of the four items in the wellness index. Wellness did not drop before injuries, and training load explained only 7% of the variation in next-day fatigue, so most of how players feel comes from outside training.	Look at stress trends over several weeks alongside load, not day to day. Use low-wellness flags to start a conversation with the player, and help shape how the daily check-in is explained to players.
Nutrition	There is no nutrition data in this dataset. Sleep quality and sleep duration are the only related measures.	Start with simple, regular measures such as body mass, fuelling around sessions and hydration, recorded by player and date so they join the existing dashboard.
Coaches and Head of Performance	Players completed 67% of possible wellness forms (Team A 75%, Team B 56%), and 14 players reported less than half the time. Team B recorded only 4 of the 29 injuries, which most likely means injuries went unreported.	Make the check-in part of the daily routine and chase missing reports the same day, using the weekly report's list of players with no reports. Aim for 80% in both teams. Every other finding depends on this.

How To Use The Tools:

The Power BI dashboard lets each department filter by team, player and date, set their own ACWR limits with a slider, and drill through to any player's full history. The weekly report lists, every Monday, the players to speak to first and why (high or low ACWR, low wellness, high monotony or no reports).

Caveats:

All data is self-reported, there were only 29 injury episodes, and the thresholds (ACWR 0.8 and 1.5, wellness -0.5) are conventions rather than proven cut-offs. Flags are a prompt for a conversation, not a diagnosis.
